

$$L_q \rightarrow L S L S L$$

$$S_q \rightarrow L S L$$

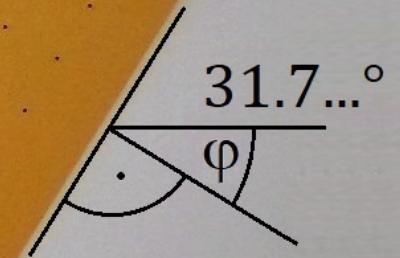

$$L_q/L = \tau^3$$

$$L/S = \tau$$

Fibonacci Chain

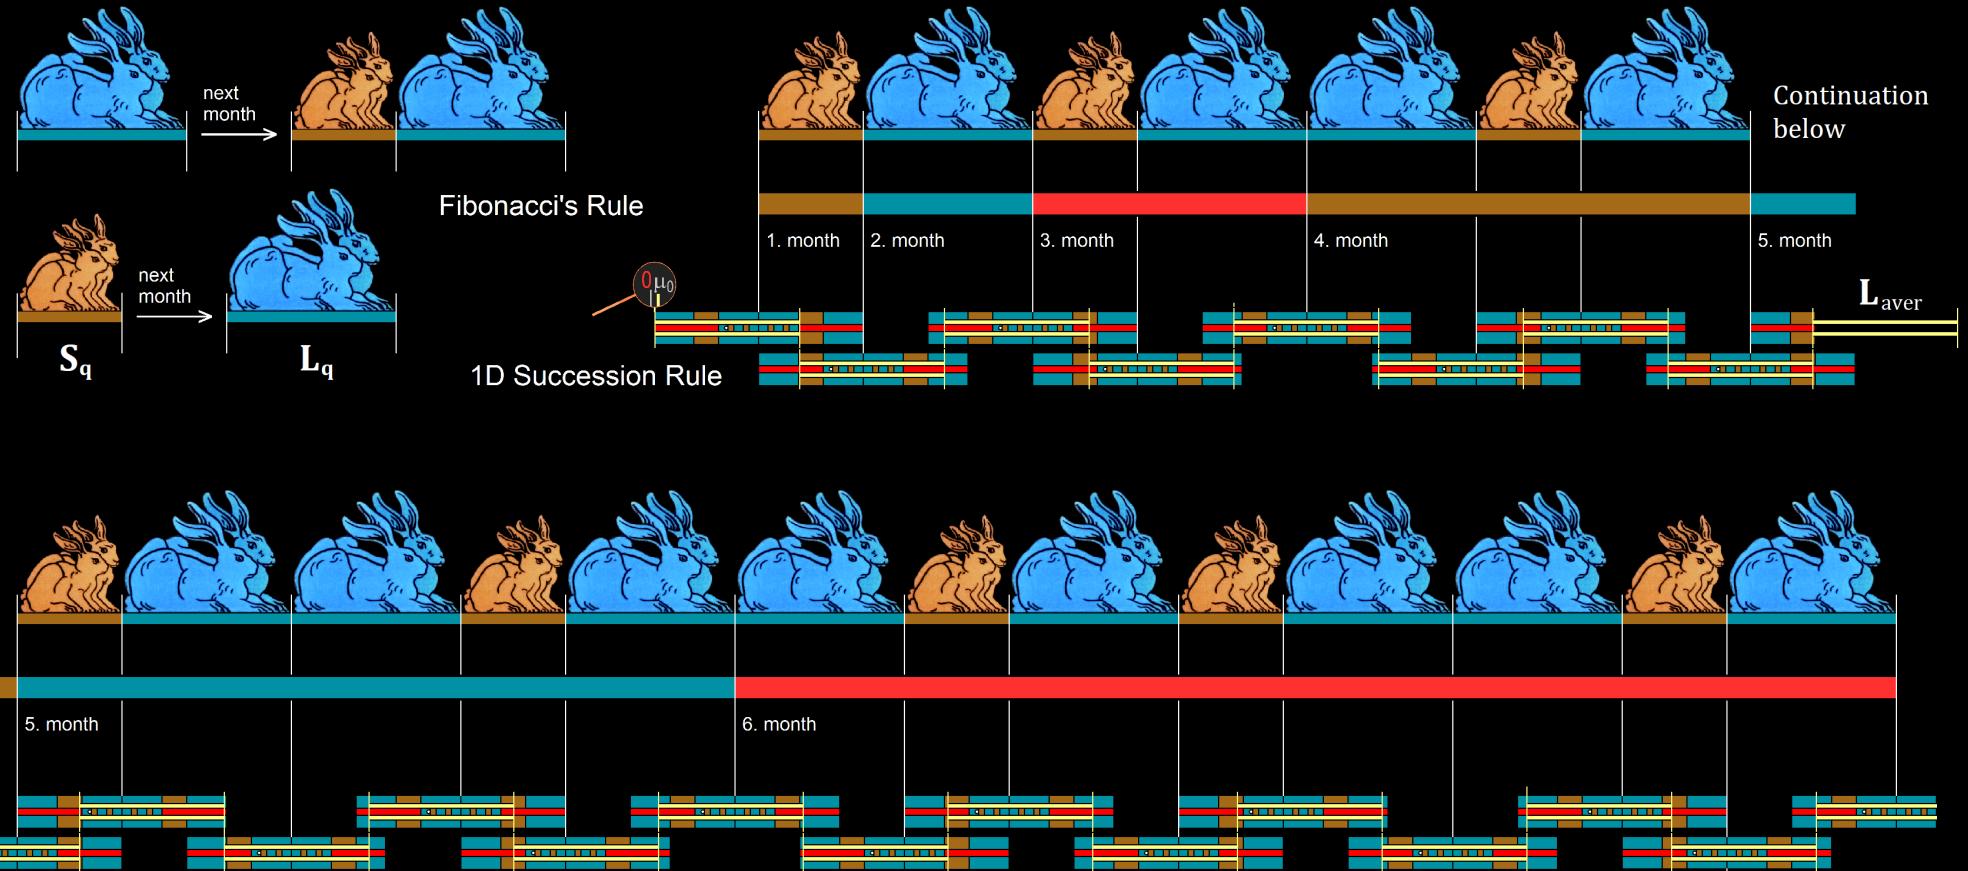

Created by substitution in the top three bars.
Created by stripe projection of square lattice points below.

$$\varphi = \arctan \tau^{-1}$$

$$\tau = 0.5 (5^{0.5} + 1)$$

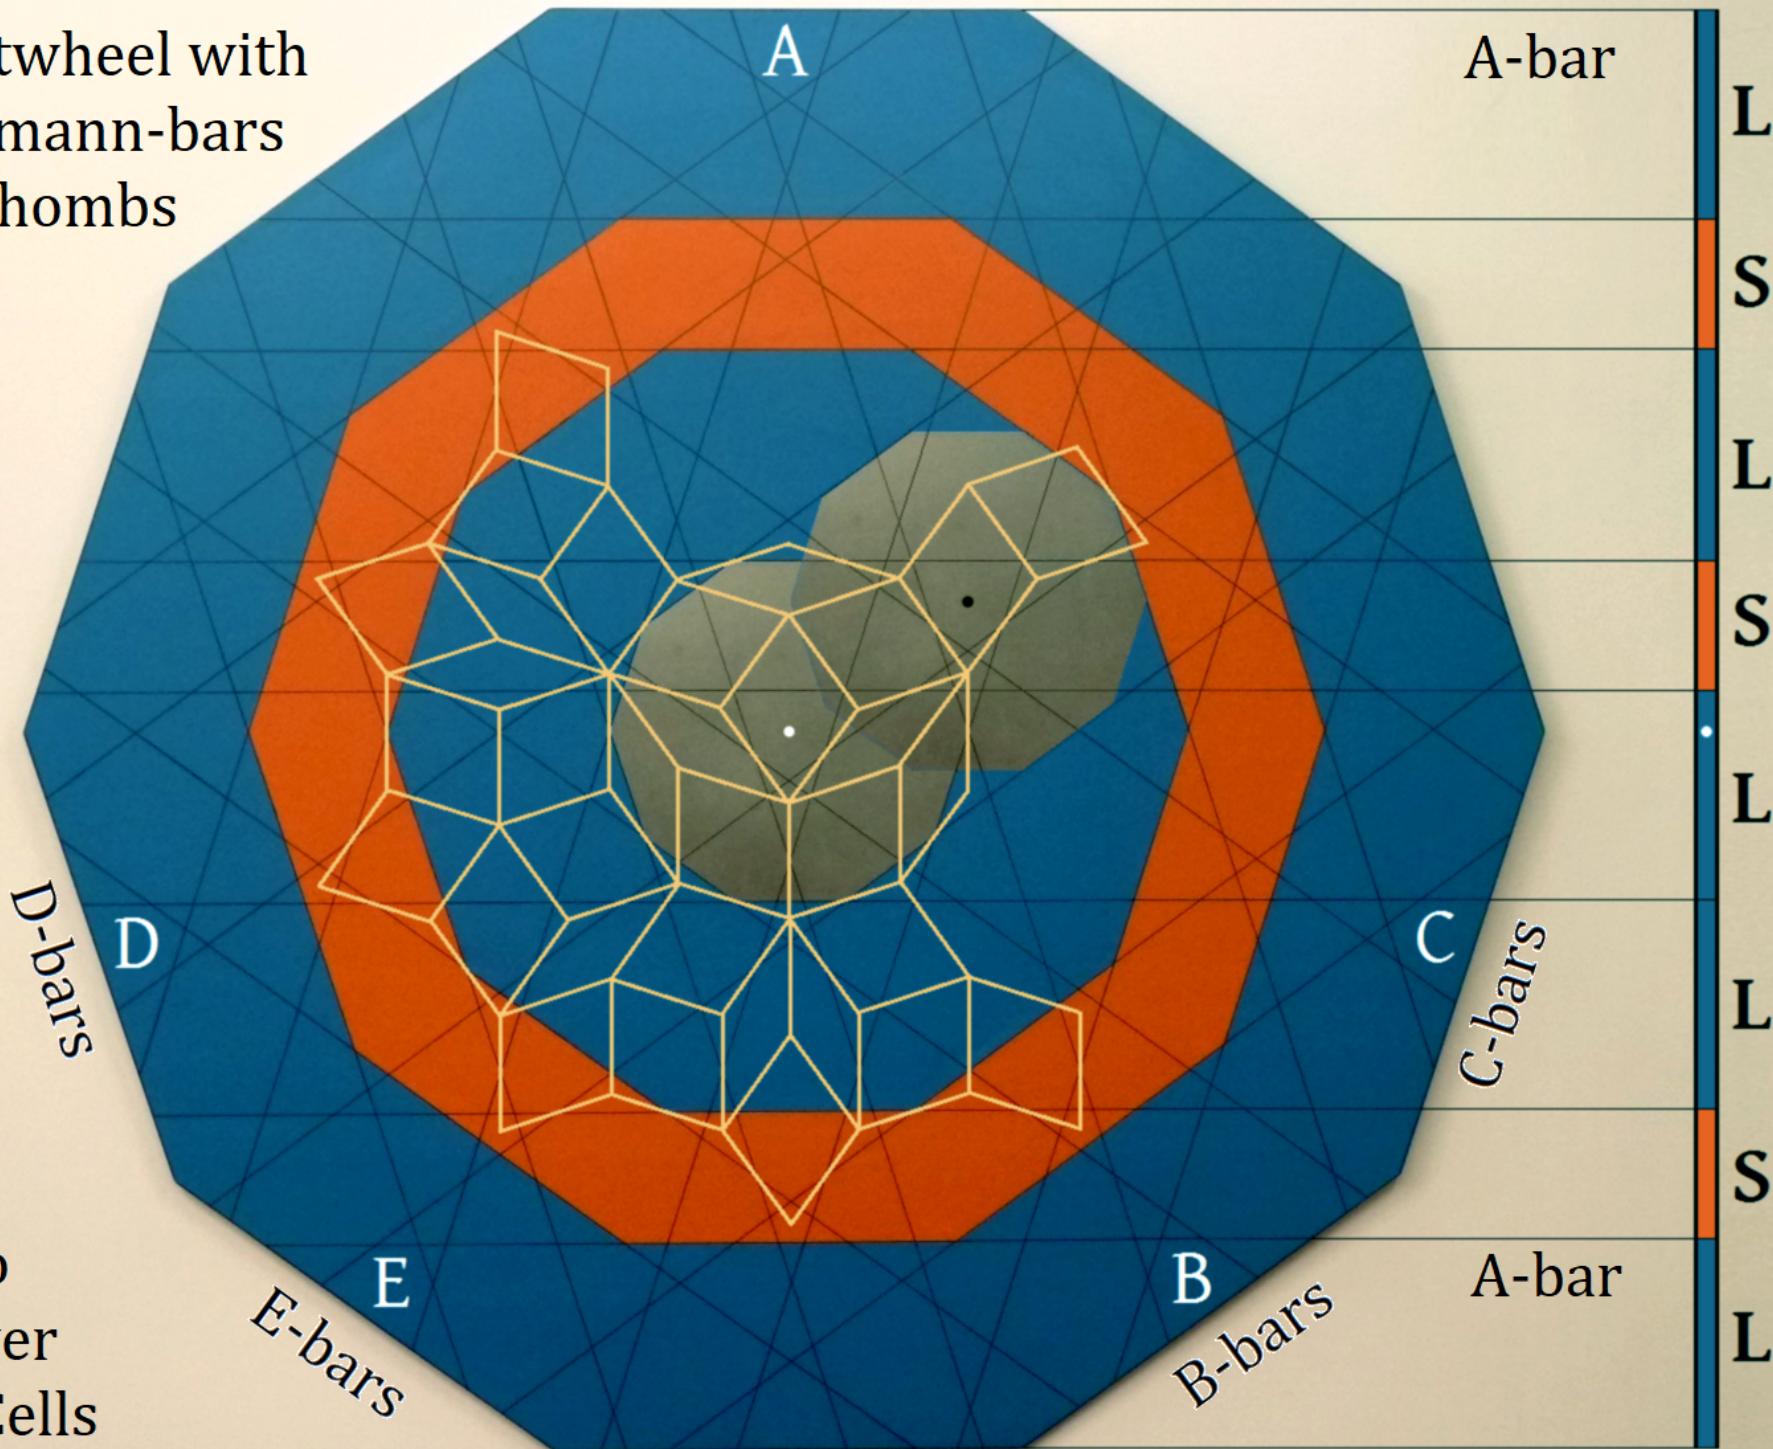

$$\tau = 1.618033988\dots$$

The first aperiodic sequence was found by Leonardo Fibonacci (c. 1170 - c. 1240-50). He described the growth of a population of rabbit couples under idealized conditions: A newborn couple is sexually mature after one month and then gives birth to another couple every month. May the rabbits be given eternal life.

Since in a Fibonacci sequence the number of adult pairs to the young pairs is approaching the golden ratio τ ($= 1.618\dots$), the sequence is suitable for modelling quasicrystals with tenfold rotational symmetry. But for this, a successively generating rule is needed. If the old and young pairs assigned lengths L_q and S_q that are in the golden ratio τ to each other, an average length L_{aver} can be calculated. With this average length, it is possible to construct quasicells Q that successively control the correct growth of the Fibonacci sequence.
