Abstract

We describe a journey through our exhibition *La La Lab - the Mathematics of Music*, which mixes a laboratory format with interactive exhibits to present visitors with the historical, conceptual, and artistic connections between mathematics and music, pushing forward musical creativity, mathematical knowledge and any blending of the two.

What is *La La Lab*?

Mathematics deeply permeates all aspects of music, from the physics of sound to the crafting of instruments, from rhythmic patterns to tonal harmony, from classical to electronic music. Mathematics supports music and our understanding of art the same way as it supports physics and our understanding of the world. Hearing music through a mathematical lens brings understanding to the music lover, appreciation for details, and a greater enjoyment of the art; and to professionals the ability to compose music as well as tools to express their creativity.

We aim to convey this idea to the general public, using the format of an interactive exhibition. This form of communication and outreach, together with artistic exhibits and new technologies on visualization and interactive experiences, allows us to pursue the goal of increasing sensibly the mathematical and musical culture of the visitors, while making the experience entertaining, creative, and playful.

La La Lab - the Mathematics of Music is an exhibition created by IMAGINARY in collaboration with artists and experts in current research of music and mathematics around the world, combining a laboratory format with interactive exhibits. All the exhibits are open source and can be downloaded from our platform imaginary.org to play and explore deeper or to create your own exhibition [5]. It was first displayed at the Mathematics Informatics Station (MAINS) in Heidelberg, Germany, from May 2019 to March 2020 and will be exhibited at different venues in the future. MAINS is a project of the Heidelberg Laureate Forum Foundation (HLFF) [3], which strives to show how stimulating mathematics and computer science can be and how important their roles are in today's world.

In the following, we will give a short walk-through and introduction to the exhibits. The name of each of the 22 exhibits of *La La Lab* is identified in bold. Most of the exhibits can be played online on the aforementioned platform [5], where videos and complementary material are also available. More in-depth explanations can be found in the extensive booklet [4] that we prepared for visitors of *La La Lab*.

Mathematics of Classical Music Theory

La La Lab is a journey about how music works, how it is built, how it is felt, and what role the underlying mathematics plays in music. Our trip begins with the first thing we need in order to create music: sound. With **The Spectrum of Sound** visitors can explore acoustics and Fourier theory within a two screen exhibit: On the first touch screen there is a spectrum analyzer attached to a microphone, on the second one a graphical synthesizer is shown together with a speaker (Figure 1, middle and right). With these tools different sounds can be merged and decomposed into frequencies. These sounds can be produced synthetically, come from real musical instruments or from the visitor's own voice. The voice, by the way, is the oldest and most

versatile musical instrument, which we can all play. The exhibit **Pink Trombone** offers a mathematical model of the human voice that the visitors can control and hear while graphically manipulating an image of the vocal tract with several fingers via the touch display.

We have now sound and instruments, but we don't use every sound to make music, we select some pitches to build a set of notes (a scale) to tune instruments and make music by combining these notes. In the **Scale Lab** exhibit (Figure 1, left) several tools are offered to visualize and understand the frequency combinations that form the basis of harmony in a scale. Visitors can compare different tunings, scales used around the world, or create their own scale. The **Note Compass** exhibit offers another perspective: all possible diatonic scales in the modern Western music are organized by their functional relations, not just by their acoustics.

Figure 1: *Scale Lab and Spectrum of Sound (Analyzer and Synthesizer).*

We have figured out what scales are, but how can we learn how to use them. The **Tonnetz** exhibit offers a graphical representation of the (Western) scale in a grid that orders notes not by their pitch, but by their affinity, by the intervals and chords that define their musical relationships. It is not only a clever representation (tracing back to Euler [2]), the geometrical properties of the Tonnetz will give much musical information, and even the geometric transformations of the Tonnetz grid will create new music pieces with astonishing harmonies.

Now that we have scales, notes and chords, we need something fundamental to make music alive, a driving force that moves the notes through time, we need rhythm. Exploring the **Beat Box** exhibit, the visitors can play with different applets based on rhythms, and discover their affinity relations based on arithmetic.

Let's put it all together and make some music based on what we have explored so far on our musical journey. With the **Graph Composer** visitors can play and create a piece of music by drawing a graph (network), where each vertex is a note and each edge defines the transitions from one note to another. This graph representation is used in research to analyze pieces and to extract features. It is equivalent to a musical score, just at a more abstract level. And here it allows many visitors to make their first basic composition.

Next, we can go explore new technologies and current research in the music field (AI exhibits), or we can go enjoy some artistic music accompanied by beautiful visuals (art exhibits and videos), or play with musical games, or wander around to find another surprise. The exhibition is not linear, the journey can be made in any order by jumping from one exhibit to another.

Artificial Intelligence and Music

Three exhibits in the collection use the latest current research in music and Artificial Intelligence (AI). With the **AI Jam** exhibit, visitors can play a duet together with an AI on a piano and percussion drum pads. The machine will try to respond to the visitor's strokes with something that is musically meaningful, according to the style that the machine has been trained with. How far can AI go in the field of music? Can a machine reach an expressive level of a human? Can we communicate what we feel expressive to a system? This is a research topic that can be discovered with **Con Espressione!**, an exhibit where the visitor takes on the role of a music conductor and the machine takes the role of a performing pianist. With hand gestures one can give

indications of tempo and loudness, and the machine will just obediently change those parameters. However, the visitor can endow the system with some AI using a slider to control its impact, and the machine will also adjust other microscopical parameters that make everything more "human". AI is not only applied in music to composition and performance, but also to sound and acoustics. With the **NSynth** exhibit, visitors can use a synthesizer and create new sounds finding an instrument that sounds somewhere between two (or up to four) examples, which can be chosen from a library, such as a trumpet and a violin, or a car engine, a piano or even the meow of a cat.

Art Combining Music and Mathematics

In the art section of the exhibition, visitors will find three exhibits based on the mathematical Lissajous figures, that visualize frequency relations of tones. On the image gallery of **Lissajous prints**, visitors can look at whimsical shapes in black and white, this is what harmony looks like in this mathematical artist's rendition (Figure 2, middle). There are also similar 3D-printed shapes on display in the exhibit **Triad Sculptures** (Figure 2, right), which visitors can touch and observe the different shadows. Similar figures can be generated by singing into the microphone of the exhibit **The Harmonic Series** (part 1: with analog laser technology combined with two microphones, part 2: with a modern 3D display which offers one microphone input and an adjustable second tone via slider, Figure 2, left). The aforementioned exhibit Scale Lab offers a tool to see the Lissajous figures of two notes, which can be played on the attached keyboard.

Figure 2: *Lissajous exhibits (3D display, pictures, and 3D-print).*

Other artistic exhibits include the mesmerizing **Whitney Music Box** (Figure 3, right), a dance of musical scales with geometric spirals, that can be controlled by turning a wheel. Or visitors can move through the space of **Pentatonic Scales** (Figure 3, left) and create their own impressionistic style music by playing pieces by classical composers with only five notes. Pentatonic scales are selections of five out of the twelve notes in our tonal system, with the restriction that no two neighbouring notes are selected. Under these conditions, there are exactly 36 pentatonic scales visitors can explore with this exhibit. Another good place to admire examples of maths in music is the **Show Me Music** station. Visitors will find short and quick visualizations of musical and acoustic effects that can be experienced with a couple of control parameters. During the visit of the exhibition, visitors may also sit down on **The Musical Bench**, which makes twinkling music when people hold the armrests while touching, kissing, or holding hands (Figure 3, middle).

Miscellaneous Exhibits

The exhibition has other modules that complement and round up the collection. The **Hands-on Table** invites visitors to start exploring and tinkering. They may also spend some time watching artistic and insightful short movies in the **Film Station** (quite a few of the selected films had originally been screened at *The Bridges Short Film Festival*). The exhibition features a so-called **Silent-area**, where visitors can sit in the library to rest and deepen their understanding by browsing some articles and books with background information. They can be inspired by the **Mind and Music Jukebox** listening to the music that the greatest minds of mathematics and
